

Modeling the TANF Caseload in Colorado: Preliminary Findings from the Colorado Works Caseload Modeling Project

Burt S. Barnow, Johns Hopkins University Mike Mueller, The Lewin Group

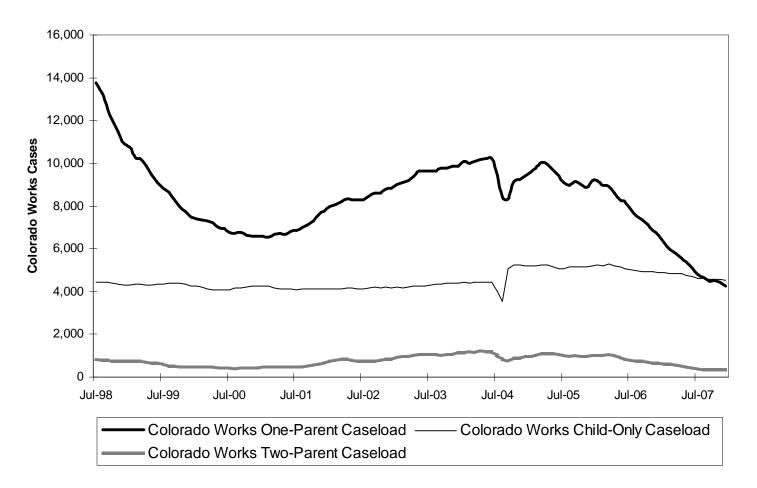

Prepared for the ACF/OPRE11th Annual Welfare Research and Evaluation Conference Washington, DC May 29, 2008

Project Background

- Purpose of the project: To develop statistical models that determine the effects the economy, population, and program have on the size of the Colorado Works caseload from July 1999 to December 2007
- Approach: Data on potential factors is analyzed using regression analysis to determine the impact on the caseload and to predict how changes might affect caseload size in the future
- Limitations:
 - For time series data, many factors change at the same time
 - Some important variables are not available for the analysis
 - Some potential factors do not vary in the period studied
- All of these factors can lead to incorrect estimates

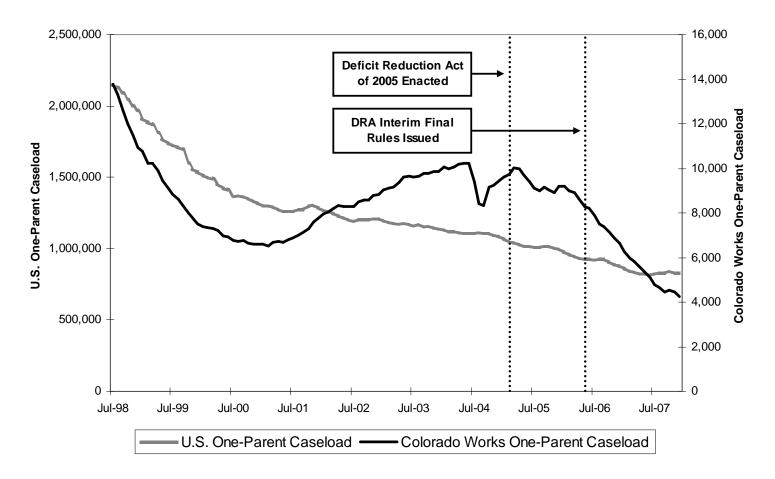

The One-Parent Caseload Has Varied Significantly, but the Others Have Remained Flat

Recent Trends in the Colorado Works One-Parent, Two-Parent and Child-Only Caseloads

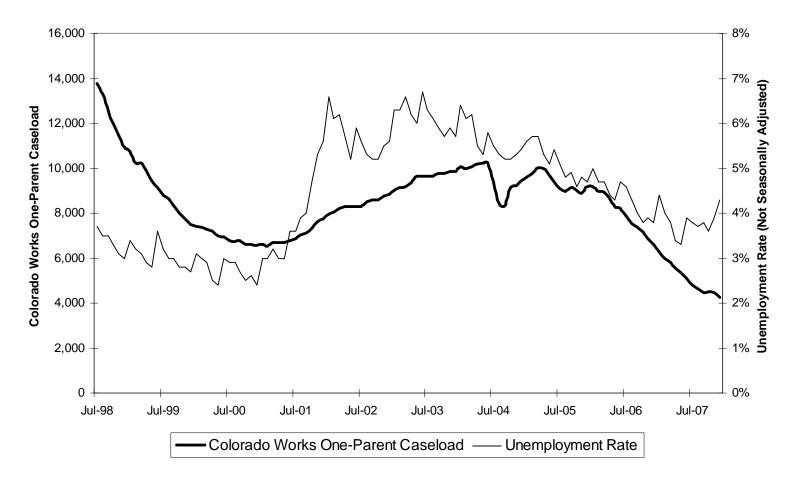

Colorado Has Had More Variation in the Size of the Caseload than National Trend

Colorado Works and U.S. One-Parent Caseloads in Relation to Federal Policy Changes

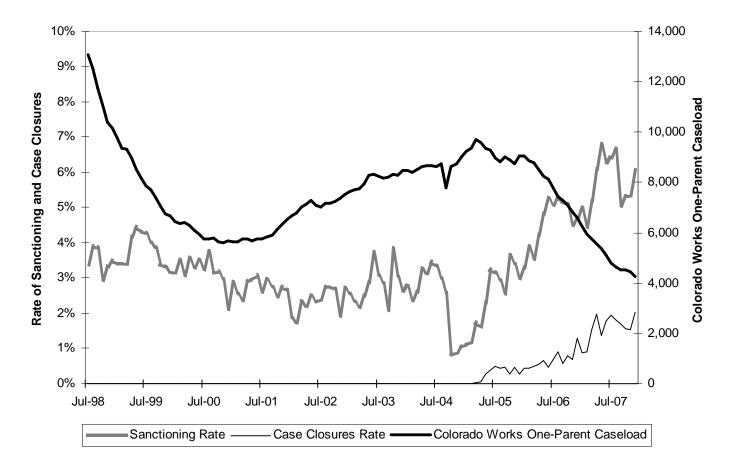

The One-Parent Caseload Varies with the Unemployment Rate

Colorado Works One-Parent Caseload and the Colorado Unemployment Rate

The Sanction Rate is Inversely Related to the Caseload Size

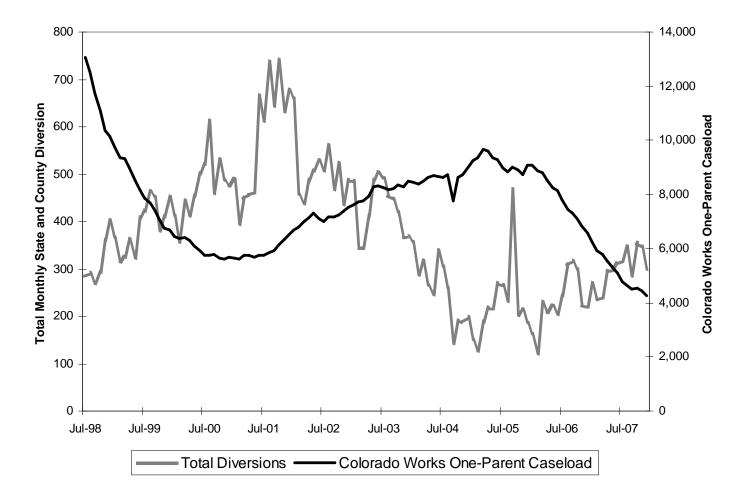

Rates of Formal Sanctioning and Administrative Case Closures for Demonstrable Evidence in the Colorado Works One-Parent Caseload

6

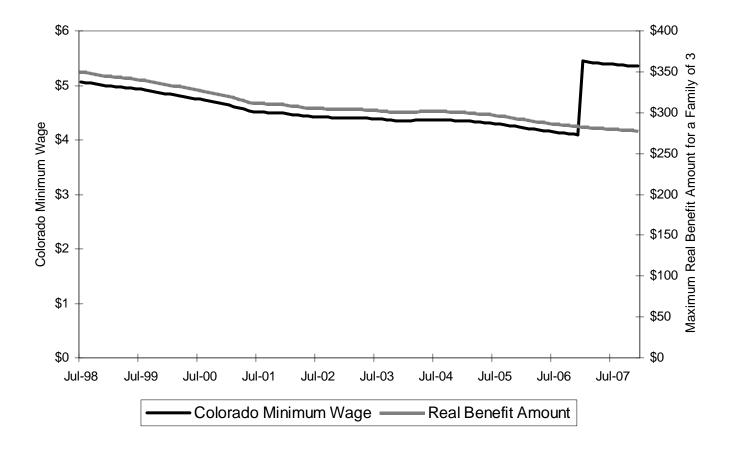

Diversions are Negatively Associated with Caseload Size

Total Diversions Paid in Colorado Works

The Inflation-Adjusted Maximum Benefit and Minimum Wage Declined Over the Years Studied

Family of Three Maximum Benefit and Colorado Minimum Wage (Inflation Adjusted to 1998 Dollars)

The Unemployment Rate for the Most Recent Three Years is the Key Factor Affecting the One-Parent Caseload

Both Stock Model and Entry/Exit Model do a Good Job of Tracking the One-Parent Caseload

Actual versus Simulated Colorado Works One-Parent Caseloads

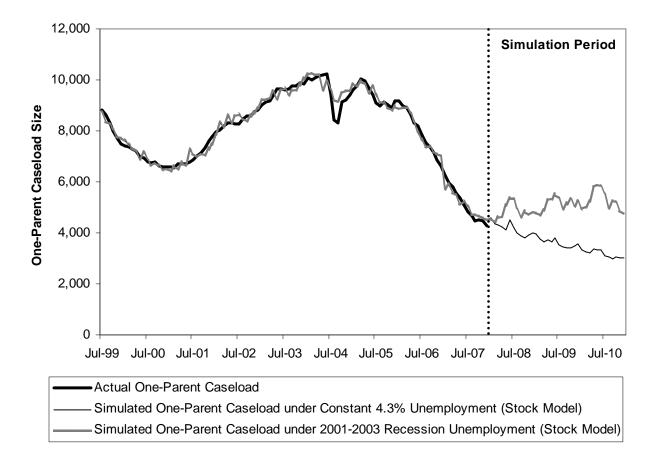

Entry-Exit Models Perform Better than Stock Model in Out-of-Sample Test

Out-of-sample Test of Regression Simulated Caseloads

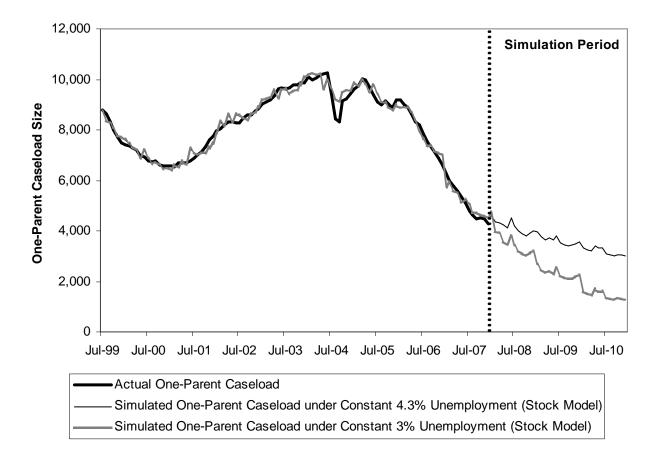

If the Unemployment Rate Rises to 2001-2003 Levels, the One-Parent Caseload is Predicted to Rise by about 1,750 Cases

Simulated One-Parent Caseload in 2008, 2009, 2010 Assuming 2001-2003 Recession Level Unemployment

If the Unemployment Rate Falls to 3%, the One-Parent Caseload is Predicted to Fall by about 1,750 Cases

Simulated One-Parent Caseload in 2008, 2009, and 2010 assuming Unemployment Rates of 3 Percent

Conclusions

- Both stock and entry/exit models fit the Colorado caseload data reasonably well
- Entry/exit models do better at predicting out-of-sample caseload than stock model
- Unemployment rate over prior three years is most important determinant of the caseload for one-parent and two-parent caseloads
- The downward trend beginning in 2005 is not easy to explain: Some may be due to DRA, but policies were implemented by state and counties at varying times
- Data limitations and limited observations preclude estimating all models of interest
